

Part IA - Dynamics and Relativity

Lectured by G. I. Ogilvie

Lent 2015

Basic concepts

Space and time, frames of reference, Galilean transformations. Newton's laws. Dimensional analysis. Examples of forces, including gravity, friction and Lorentz. [4]

Newtonian dynamics of a single particle

Equation of motion in Cartesian and plane polar coordinates. Work, conservative forces and potential energy, motion and the shape of the potential energy function; stable equilibria and small oscillations; effect of damping.

Angular velocity, angular momentum, torque.

Orbits: the $u(\theta)$ equation; escape velocity; Kepler's laws; stability of orbits; motion in a repulsive potential (Rutherford scattering). Rotating frames: centrifugal and coriolis forces. *Brief discussion of Foucault pendulum.* [8]

Newtonian dynamics of systems of particles

Momentum, angular momentum, energy. Motion relative to the centre of mass; the two body problem. Variable mass problems; the rocket equation. [2]

Rigid bodies

Moments of inertia, angular momentum and energy of a rigid body. Parallel axes theorem. Simple examples of motion involving both rotation and translation (e.g. rolling). [3]

Special relativity

The principle of relativity. Relativity and simultaneity. The invariant interval. Lorentz transformations in $(1+1)$ -dimensional spacetime. Time dilation and length contraction. The Minkowski metric for $(1+1)$ -dimensional spacetime. Lorentz transformations in $(3+1)$ dimensions. 4-vectors and Lorentz invariants. Proper time. 4-velocity and 4-momentum. Conservation of 4-momentum in particle decay. Collisions. The Newtonian limit. [7]

1 Newtonian dynamics of particles

We start with a few basic definitions:

Definition (Particle). An *particle* is an object of insignificant size. It can be regarded as a point. It has a *mass* $m > 0$, and *electric charge* q .

Its position at time t is described by its *position vector*, $\mathbf{r}(t)$ or $\mathbf{x}(t)$ with respect to an origin O .

Definition (Frame of reference). A *frame of reference* is choice of coordinate axes for \mathbf{r} . The axes may be fixed, moving, or accelerating relative to another frame.

With a frame of reference, we can write \mathbf{r} in cartesian coordinates as (x, y, z)

Definition (Velocity). The *velocity* of the particle is

$$\mathbf{v} = \dot{\mathbf{r}} = \frac{d\mathbf{r}}{dt}.$$

and is tangent to the path or trajectory.

Definition (Acceleration). The *acceleration* of the particle is

$$\mathbf{a} = \dot{\mathbf{v}} = \ddot{\mathbf{r}} = \frac{d^2\mathbf{r}}{dt^2}.$$

Definition (Momentum). The *momentum* of a particle is

$$\mathbf{p} = m\mathbf{v} = m\dot{\mathbf{r}}.$$

m is the *inertial mass* of the particle, and measures its reluctance to accelerate (c.f. Newton's Second Law)

1.1 Newton's laws of motion

We begin by stating Newton's three laws of motion:

Law (Newton's First Law of Motion). A body remains at rest, or moves uniformly in a straight line, unless acted on by a force. (This is in fact Galileo's Law of Inertia)

Law (Newton's Second Law of Motion). The rate of change of momentum of a body is equal to the force acting on it (in both magnitude and direction).

Law (Newton's Third Law of Motion). To every action there is an equal and opposite reaction: the forces of two bodies on each other are equal and in opposite directions.

The first law might seem redundant given the second if interpreted literally. Therefore, we should be interpreting it in the different way:

Note that the first law isn't always true. Take yourself as a frame of reference. When you move around your room, things will seem like they are moving around (relative to you). When you sit down, they stop moving. However, on second thought, this is because you, the frame of reference, is accelerating, not the objects. The first law only holds in frames that are themselves not accelerating. We call these *inertial frames*.

Definition (Inertial frames). *Inertial frames* are frames of references in which the frames themselves are not accelerating. Newton's Laws only hold in inertial frames.

The we can take the first law to assert that inertial frames exists. Even though the Earth itself is rotating and orbiting the sun, for most purposes, any fixed place on the Earth counts as an inertial frame.

1.2 Galilean transformations

Inertial frames aren't unique. If S is an inertial frame, then any other frame S' in uniform motion relative to S is also inertial:

Assuming the frames coincide at $t = 0$, then

$$\begin{aligned}x' &= x - vt \\y' &= y \\z' &= z \\t' &= t\end{aligned}$$

Generally, the position vector transforms as

$$\mathbf{r}' = \mathbf{r} - \mathbf{v}t,$$

where \mathbf{v} is the (constant) velocity of S' relative to S . The velocity and acceleration transform as follows:

$$\begin{aligned}\dot{\mathbf{r}}' &= \dot{\mathbf{r}} - \mathbf{v} \\\ddot{\mathbf{r}}' &= \ddot{\mathbf{r}}\end{aligned}$$

Definition (Galilean boost). A Galilean boost is a change in frame of reference by

$$\begin{aligned}\mathbf{r}' &= \mathbf{r} - \mathbf{v}t \\t' &= t\end{aligned}$$

for a fixed, constant \mathbf{v} .

In addition to Galilean boosts, we can construct new inertial frames by applying (any combination of) the following:

- Translations of space:

$$\mathbf{r}' = \mathbf{r} - \mathbf{r}_0$$

- Translations of time:

$$t' = t - t_0$$

- Rotation (and reflection):

$$\mathbf{r}' = R\mathbf{r}$$

with $R \in O(3)$.

These transformations together generate the Galilean group.

Law (Galilean relativity). The *principle of relativity* asserts that the laws of physics are the same in inertial frames.

This implies that physical processes work the same

- at every point of space
- at all times
- in whichever direction we face
- at whatever constant velocity we travel.

In other words, the equations of Newtonian physics must have *Galilean invariance*.

Since the laws of physics are the same regardless of your velocity, velocity must be a *relative concept*, and there is no such thing as an “absolute velocity” that all inertial frames agree on.

However, all inertial frames must agree on whether you are accelerating or not (even though they need not agree on the direction of acceleration since you can rotate your frame). So acceleration is an *absolute* concept.

1.3 Newton’s Second Law

Law. The *equation of motion* for a particle subject to a force F is

$$\frac{d\mathbf{p}}{dt} = \mathbf{F},$$

where $\mathbf{p} = m\mathbf{v} = m\dot{\mathbf{r}}$ is the (linear) momentum of the particle. We say m is the (inertial) mass of the particle, which is a measure of its reluctance to accelerate.

Usually, m is constant. Then

$$\mathbf{F} = m\mathbf{a} = m\ddot{\mathbf{r}}.$$

If \mathbf{F} is specified as a function of $\mathbf{r}, \dot{\mathbf{r}}$ and t , then we have a second-order ordinary differential equation for \mathbf{r} .

To determine the solution, we need to specify the initial values of \mathbf{r} and $\dot{\mathbf{r}}$, i.e. the initial position and velocity. The trajectory of the particle is then uniquely determined for all future (and past) times.

2 Dimensional Analysis

Physical quantities are not pure numbers, but have *dimensions*. In any equation, the dimensions have to be consistent.

For many problems in dynamics, three basic dimensions are sufficient:

- length, L
- mass, M
- time, T

The dimensions of a physical quantity X , denoted as $[X]$ are expressible uniquely in terms of L , M and T , e.g.

- $[\text{area}] = L^2$
- $[\text{density}] = L^{-3}M$
- $[\text{velocity}] = LT^{-1}$
- $[\text{acceleration}] = LT^{-2}$
- $[\text{force}] = LMT^{-2}$ since the dimensions must satisfy the equation $F = ma$.
- $[\text{energy}] = L^2MT^{-2}$, e.g. consider $E = mv^2/2$.

Physical constants also have dimensions, e.g. $[G] = L^3M^{-1}T^{-2}$ by $F = GMm/r^2$.

We can only take sums and products of terms that have dimensions, and if we sum two terms, they must have the same dimension. More complicated

functions of dimensional quantities are not allowed, e.g. e^x makes no sense if x has a dimension, since

$$e^x = 1 + x + \frac{1}{2}x^2 + \dots$$

and if x had a dimension, we would be summing up terms of different dimensions.

2.1 Units

A *unit* is a convenient standard physical quantity. In the SI system, there are base units corresponding to the basic dimensions. The three we need are

- meter (m) for length
- kilogram (kg) for mass
- second (s) for time

A physical quantity can be expressed as a pure number times a unit with the correct dimensions, e.g.

$$G = 6.67 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}.$$

It is important to realize that SI units are chosen arbitrarily for historical reasons only. The equation of physics must work in any consistent system of units. This is captured by the fact that physical equations must be dimensionally consistent.

2.2 Scaling

Suppose we believe that a physical quantity Y depends on 3 other physical quantities X_1, X_2, X_3 , i.e. $Y = Y(X_1, X_2, X_3)$. Let their dimensions be as follows:

- $[Y] = L^a M^b T^c$
- $[X_i] = L^{a_i} M^{b_i} T^{c_i}$

Suppose further that we know that the relationship is a power law, i.e.

$$Y = C X_1^{p_1} X_2^{p_2} X_3^{p_3},$$

where C is a dimensionless constant (i.e. pure number). Since the dimensions must work out, we know that

$$\begin{aligned} a &= p_1 a_1 + p_2 a_2 + p_3 a_3 \\ b &= p_1 b_1 + p_2 b_2 + p_3 b_3 \\ c &= p_1 c_1 + p_2 c_2 + p_3 c_3 \end{aligned}$$

for which there is a unique solution provided that the dimensions of X_1, X_2 and X_3 are independent.
