# Part IA - Numbers and Sets Theorems with Proof

# Lectured by A. G. Thomason

#### Michaelmas 2014

#### Introduction to number systems and logic

Overview of the natural numbers, integers, real numbers, rational and irrational numbers, algebraic and transcendental numbers. Brief discussion of complex numbers; statement of the Fundamental Theorem of Algebra.

Ideas of axiomatic systems and proof within mathematics; the need for proof; the role of counter-examples in mathematics. Elementary logic; implication and negation; examples of negation of compound statements. Proof by contradiction. [2]

#### Sets, relations and functions

Union, intersection and equality of sets. Indicator (characteristic) functions; their use in establishing set identities. Functions; injections, surjections and bijections. Relations, and equivalence relations. Counting the combinations or permutations of a set. The Inclusion-Exclusion Principle.

#### The integers

The natural numbers: mathematical induction and the well-ordering principle. Examples, including the Binomial Theorem. [2]

### Elementary number theory

Prime numbers: existence and uniqueness of prime factorisation into primes; highest common factors and least common multiples. Euclids proof of the infinity of primes. Euclids algorithm. Solution in integers of ax + by = c.

Modular arithmetic (congruences). Units modulo n. Chinese Remainder Theorem. Wilson's Theorem; the Fermat-Euler Theorem. Public key cryptography and the RSA algorithm. [8]

#### The real numbers

Least upper bounds; simple examples. Least upper bound axiom. Sequences and series; convergence of bounded monotonic sequences. Irrationality of  $\sqrt{2}$  and e. Decimal expansions. Construction of a transcendental number. [4]

#### Countability and uncountability

Definitions of finite, infinite, countable and uncountable sets. A countable union of countable sets is countable. Uncountability of R. Non-existence of a bijection from a set to its power set. Indirect proof of existence of transcendental numbers. [4]

# 1 Sets, functions and relations

#### 1.1 Sets

**Theorem.**  $(A = B) \Leftrightarrow (A \subseteq B \text{ and } B \subseteq A)$ 

Proposition.

- $(A \cap B) \cap C = A \cap (B \cap C)$
- $(A \cup B) \cup C = A \cup (B \cup C)$
- $-A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$

# 1.2 Functions

**Theorem.** The left inverse of A exists iff f is injective.

*Proof.* ( $\Rightarrow$ ) If the left inverse g exists, then  $\forall a, a' \in A, f(a) = f(a') \Rightarrow g(f(a)) = g(f(a')) \Rightarrow a = a'$ . Therefore f is injective.

 $(\Leftarrow)$  if f is injective, we can construct a g defined as

$$g: \begin{cases} g(b) = a & \text{if } b \in f(A), \text{ where } f(a) = b \\ g(b) = \text{anything} & \text{otherwise} \end{cases}.$$

Then g is a left inverse of f.

**Theorem.** The right inverse of A exists iff f is surjective.

*Proof.* ( $\Rightarrow$ ) We have f(g(B)) = B since  $f \circ g$  is the identity function. Thus f must be surjective since its image is B.

 $(\Leftarrow)$  If f is surjective, we can construct a g such that for each  $b \in B$ , pick one  $a \in A$  with f(a) = b, and put g(b) = a.

*Note*: This proof relies on the Axiom of Choice (in fact this theorem and the Axiom of Choice are equivalent).  $\Box$ 

#### 1.3 Relations

**Theorem.** If  $\sim$  is an equivalence relation on A, the equivalence classes of  $\sim$  form a partition of A.

*Proof.* By reflexivity, we have  $a \in [a]$ . Thus the equivalence classes cover the whole set. We must now show that for all  $a, b \in A$ , either [a] = [b] or  $[a] \cap [b] = \emptyset$ .

Suppose  $[a] \cap [b] \neq \emptyset$ . Then  $\exists c \in [a] \cap [b]$ . So  $a \sim c, b \sim c$ . By symmetry,  $c \sim b$ . By transitivity, we have  $a \sim b$ . For all  $b' \in [b]$ , we have  $b \sim b'$ . Thus by transitivity, we have  $a \sim b'$ . Thus  $[b] \subseteq [a]$ . By symmetry,  $[a] \subseteq [b]$  and [a] = [b].

# 2 Division

# 2.1 Euclid's Algorithm

**Theorem** (Division Algorithm). Given  $a, b \in \mathbb{Z}$ , there are unique  $q, r \in \mathbb{Z}$  with a = qb + r and  $0 \le r < b$ .

*Proof.* Choose  $q = \max\{q : qb \le n\}$ . This maximum exists because the set of all q such that  $qb \le n$  is finite. Now write r = a - qb. We have  $0 \le r < b$  and thus q and r are found.

To show that they are unique, suppose that a = qb + r = q'b + r'. We have (q - q')b = (r' - r). Since both r and r' are between 0 and b, we have -b < r - r' < b. However, r' - r is a multiple of b. Thus q - q' = r' - r = 0. Consequently, q = q' and r = r'.

**Proposition.** If c|a and c|b, c|(ua+vb) for all  $u,v \in \mathbb{Z}$ .

*Proof.* By definition, we have a = kc and b = lc. Then ua + vb = ukc + vlc = (uk + vl)c and c|(ua + vb).

**Theorem.** Let  $a, b \in \mathbb{N}$ . Then (a, b) exists.

*Proof.* Let  $S = \{ua + vb : i, v \in \mathbb{Z}\}$  be the set of all linear combinations of a, b. Let d be the smallest positive member of S. Say d = xa + yb. If c|a, c|b, then c|d. So we need to show that d|a and d|b, and thus d = (a, b).

By the division algorithm, there exists numbers  $q, r \in \mathbb{Z}$  with a = qd + r with  $0 \le r < d$ . Then r = a - qd = a(1 - qx) - qyb. Therefore r is a linear combination of a and b. Since d is the smallest positive member of S and  $0 \le r < d$ , we have r = 0 and d|a. Similarly, we can show that d|b.

**Corollary.** (from the proof) Let d = (a, b), then d is the smallest positive linear combination of a and b.

**Corollary** (Bézout's identity). Let  $a, b \in \mathbb{N}$  and  $c \in \mathbb{Z}$ . Then there exists  $u, v \in \mathbb{Z}$  with c = ua + vb iff (a, b)|c.

*Proof.* ( $\Rightarrow$ ) Let d = (a,b). If c is a linear combination of a and b, then d|c because d|a and d|b.

( $\Leftarrow$ ) Suppose that d|c. Let d=xa+yb and c=kd. Then c=(kx)a+(ky)b. Thus c is a linear combination of a and b.

**Proposition** (Euclid's Algorithm). If we continuously break down a and b by the following procedure:

$$a = q_1b + r_1$$

$$b = q_2r_1 + r_2$$

$$r_1 = q_3r_2 + r_3$$

$$\vdots$$

$$r_{n-2} = q_nr_{n-1}$$

then the highest common factor is  $r_{n-1}$ .

*Proof.* We have common factors of a, b = common factors of  $b, r_1 =$  common factors of  $r_1, r_2 = \cdots =$  factors of  $r_{n-1}$ .

#### 2.2 Primes

**Theorem.** Every number can be written as a product of primes.

*Proof.* If  $n \in \mathbb{N}$  is not a prime itself, then by definition n = ab. If either a or b is not prime, then that number can be written as a product, say b = cd. Then n = acd and so on. (Rigorous proof by strong induction) Since these numbers are getting smaller, and the process will stop when they are all prime.

**Theorem.** There are infinitely many primes.

*Proof.* (Euclid's proof) Suppose there are finitely many primes, say  $p_1, p_2 \cdots p_n$ . Then  $N = p_1 p_2 \cdots p_n + 1$  is divisible by none of the primes. Otherwise,  $p_j | (N - p_1 p_2 \cdots p_n)$ , i.e.  $p_j | 1$ , which is impossible. However, N is a product of prime, so there must be primes not amongst  $p_1, p_2 \cdots p_n$ .

*Proof.* (Erdös 1930) Suppose that there are finitely many primes,  $p_1, p_2 \cdots p_n$ . Consider all numbers that are the products of these primes, i.e.  $p_1^{j_1} p_2^{j_2} \cdots p_n^{j_n}$ , where  $k_i \geq 0$ . Factor out all squares to obtain the form  $m^2 p_1^{i_1} p_2^{i_2} \cdots p_n^{i_n}$ , where  $m \in \mathbb{N}$  and  $i_k = 0$  or 1.

Let  $N \in \mathbb{N}$ . Given any number  $x \leq N$ , when put in the above form, we have  $m \leq \sqrt{N}$ . So there are at most  $\sqrt{N}$  possible values of m. For each m, there are  $2^k$  numbers of the form  $m^2 p_1^{i_1} p_2^{i_2} \cdots p_n^{i_n}$ . So there are only  $\sqrt{N} \times 2^k$  possible values of x of this kind.

Now pick  $N \geq 4^k$ . Then  $N > \sqrt{N} \times 2^k$ . So there must be a number  $\leq N$  not of this form, i.e. it has a prime factor not in this list.

**Theorem.** If a|bc and (a,b)=1, then a|c.

*Proof.* From Euclid's algorithm, there exists integers  $u, v \in \mathbb{Z}$  such that ua+vb=1. So multiplying by c, we have uac+vbc=c. Now a|LHS. So a|c.

**Corollary.** If p is a prime and p|ab, then p|a or p|b. (True for all p, a, b)

*Proof.* Consider (p, a) = p or 1 because p is a prime. if (p, a) = p, then p|a. Otherwise, (p, a) = 1 and p|b by the theorem above.

**Corollary.** If p is a prime and  $p|n_1n_2\cdots n_i$ , then  $p|n_i$  for some i.

**Theorem** (Fundamental Theorem of Arithmetic). Every natural number is expressible as a product of primes in exactly one way. In particular, if  $p_1p_2\cdots p_k=q_1q_2\cdots q_l$ , where  $p_i,q_i$  are primes but not necessarily distinct, then k=l.  $q_1,\cdots q_l$  are  $p_1,\cdots p_k$  in some order. Since we already showed at least one way above, we only need to show uniqueness.

*Proof.* Let  $p_1 \cdots p_k = q_1 \cdots q_l$ . We know that  $p_1|q_1 \cdots q_l$ . Then  $p_1|q_1(q_2q_3 \cdots q_l)$ . Thus  $p_1|q_i$  for some i. wlog assume i=1. Then  $p_1=q_1$  since both are primes. Thus  $p_2p_3 \cdots p_k = q_2q_3 \cdots q_l$ . Likewise, we have  $p_2=q_2, \cdots$  and so on.

**Corollary.** If  $a = p_1^{i_1} p_2^{i_2} \cdots p_r^{i_r}$  and  $b = p_1^{j_1} p_2^{j_2} \cdots p_r^{j_r}$ , where  $p_i$  are distinct primes (exponents can be zero). Then  $(a,b) = \prod p_k^{\min\{i_k,j_k\}}$ . However, this is not an efficient way to calculate (a,b). Likewise,  $\operatorname{lcm}(a,b) = \prod p_k^{\max\{i_k,j_k\}}$ . We have  $\operatorname{hcf}(a,b) \times \operatorname{lcm}(a,b) = ab$ .

# 3 Counting and Integers

**Theorem** (Pigeonhole Principle). Given (m-1)n+1 pigeons and n pigeonholes, some pigeonhole has at least m pigeons.

# Proposition.

(i) 
$$i_A = i_B \Leftrightarrow A = B$$

(ii) 
$$i_{A \cap B} = i_A i_B$$

(iii) 
$$i_{\bar{A}} = 1 - i_A$$

(iv) 
$$i_{A\cup B} = 1 - i_{\overline{A\cup B}} = 1 - i_{\overline{A}\cap \overline{B}} = 1 - i_{\overline{A}}i_{\overline{B}} = 1 - (1 - i_A)(1 - i_b) = i_A + i_B - i_{A\cap B}$$
.

(v) 
$$i_{A \setminus B} = i_{A \cap \bar{B}} = i_A i_{\bar{B}} = i_A (1 - i_B) = i_A - i_{A \cap B}$$

**Proposition.** 
$$|A \cup B| = |A| + |B| - |A \cap B|$$

Proof.

$$\begin{split} |A \cup B| &= \sum_{x \in X} i_{A(x) \cup B(x)} \\ &= \sum_{x \in X} (i_A(x) + i_B(x) - i_{A \cap B}(x)) \\ &= \sum_{x \in X} i_A(x) + \sum_{x \in X} i_B(x) - \sum_{x \in X} i_{A \cap B}(x) \\ &= |A| + |B| - |A \cap B| \end{split}$$

**Theorem** (Inclusion-Exclusion Principle). Let  $A_i$  be subsets of a finite set X, for  $1 \le i \le n$ . Then

$$|\bar{A}_1 \cap \dots \cap \bar{A}_n| = |X| - \sum_i |A_i| + \sum_{i < j} |A_i \cap A_j| - \dots + (-1)^n |A_1 \cap \dots \cap A_n|.$$

Equivalently,

$$|A_1 \cup \dots \cup A_n| = \sum_i |A_i| - \sum_{i < j} |A_i \cap A_j| + \dots + (-1)^{n-1} |A_1 \cap \dots \cap A_n|.$$

*Note*: The two forms are equivalent since  $|A_1 \cup \cdots \cup A_n| = |X| - |\bar{A}_1 \cap \cdots \cap \bar{A}_n|$ . *Proof.* Three proofs are offered:

- (i) By induction on n. (Trivial but cumbersome)
- (ii) By induction on |X|. (Trivial but cumbersome)

(iii) By indicator functions.

$$\begin{split} i_{\bar{A}_1 \cap \bar{A}_2 \cap \dots \cap \bar{A}_n} &= \prod_j i_{\bar{A}_j} \\ &= \prod_j (1 - i_{A_j}) \\ &= 1 - \sum_i i_{A_i} + \sum_{i < j} i_{A_i} i_{A_j} - \dots + (-1)^n i_{A_1} i_{A_2} \dots i_{A_n} \\ &= 1 - \sum_i i_{A_i} + \sum_{i < j} i_{A_i \cap A_j} - \dots + (-1)^n i_{A_1 \cap A_2 \cap A_3 \cap \dots \cap A_n} \end{split}$$

Thus

$$\begin{split} |\bar{A}_1 \cap \dots \cap \bar{A}_n| &= \sum_{x \in X} i_{\bar{A}_1 \cap \bar{A}_2 \cap \dots \cap \bar{A}_n}(x) \\ &= \sum_x 1 - \sum_i \sum_x i_{A_i}(x) + \sum_{i < j} \sum_x i_{A_i \cap A_j}(x) - \dots \\ &+ \sum_x (-1)^n i_{A_1 \cap A_2 \cap A_3 \cap \dots \cap A_n}(x) \\ &= |X| - \sum_i |A_i| + \sum_{i < j} |A_i \cap A_j| \\ &- \sum_{i < j < k} |A_i \cap A_j \cap A_k| + \dots + (-1)^n |A_1 \cap A_2 \cap \dots A_n| \end{split}$$

# 3.1 Combinations

**Proposition.** By definition,

$$\binom{n}{0} + \binom{n}{1} + \dots + \binom{n}{n} = 2^n$$

**Theorem** (Binomial theorem). For  $n \in \mathbb{N}$  with  $a, b \in \mathbb{R}$ , we have

$$(a+b)^{n} = \binom{n}{0}a^{n}b^{0} + \binom{n}{1}a^{n-1}b^{1} + \dots + \binom{n}{r}a^{n-r}b^{r} + \dots + \binom{n}{n}a^{0}b^{n}$$

*Proof.* We have  $(a+b)^n = (a+b)(a+b)\cdots(a+b)$ . When we expand the product, we get all terms attained by choosing a from some brackets, b from the rest. The term  $a^{n-r}b^r$  comes from choosing b from r brackets a from the rest. There are  $\binom{n}{r}$  ways to make such a choice.

# Proposition.

(i)  $\binom{n}{r} = \binom{n}{n-r}$ . This is because choosing r things to keep is the same as choosing n-r things to throw away.

(ii)  $\binom{n}{r-1} + \binom{n}{r} = \binom{n+1}{r}$  (Pascal's identity) The RHS counts the number of ways to choose a team of r players from n+1 available players, one of whom is Pietersen. If Pietersen is chosen, there are  $\binom{n}{r-1}$  ways to choose the remaining players. Otherwise, there are  $\binom{n}{r}$  ways. The total number of ways is  $\binom{n}{r-1} + \binom{n}{r}$ .

Now given that  $\binom{n}{0} = \binom{n}{n} = 1$ , since there is only one way to choose nothing or everything, we can construct *Pascal's triangle*:

where each number is the sum of the two numbers above it, and the rth item of the nth row is  $\binom{n}{r}$  (first row is row 0).

- (iii)  $\binom{n}{k}\binom{k}{r} = \binom{n}{r}\binom{n-r}{k-r}$ . LHS counts pairs of sets (Y,Z) with |Y| = k and |Z| = r with  $Z \subseteq Y$ . We first choose Y then choose  $Z \subseteq Y$ . The RHS chooses Z first and then choose the remaining  $Y \setminus Z$  from  $\{1, 2, \dots, n\} \setminus Z$ .
- (iv)  $\binom{a}{r}\binom{b}{0}+\binom{a}{r-1}\binom{b}{1}+\cdots+\binom{a}{r-k}\binom{b}{k}+\cdots\binom{a}{0}\binom{b}{r}=\binom{a+b}{r}$  (Vandermonde's convolution) Suppose we have a men and b women, and we need to choose a committee of r people. The right hand side is the total number of choices. The left hand side breaks the choices up according to the number of men vs women.

**Proposition.** 
$$\binom{n}{r} = \frac{n!}{(n-r)!r!}$$
.

*Proof.* There are  $n(n-1)(n-2)\cdots(n-r+1)=\frac{n!}{(n-r)!}$  to choose r elements in order. Each choice of subsets is chosen this way in r! orders, so the number of subsets is  $\frac{n!}{(n-r)!r!}$ .

# 3.2 Well-ordering and induction

**Theorem** (Weak Principle of Induction). Let P(n) be a statement about the natural number n. Suppose that

- (i) P(1) is true
- (ii)  $\forall n(P(n) \Rightarrow P(n+1))$

Then P(n) is true for all n > 1.

Theorem. Inclusion-exclusion principle

*Proof.* Let P(n) be the statement "for any sets  $A_1 \cdots A_n$ ", we have  $|A_1 \cup \cdots \cup A_n| = \sum_i |A_i| - \sum_{i < j} |A_i \cap A_j| + \cdots \pm |A_i \cap A_2 \cap \cdots \cap A_n|$ ".

P(1) is trivially true. P(2) is also true (see above). Now given  $A_1 \cdots A_{n+1}$ , Let  $B_i = A_i \cap A_{n+1}$  for  $i \leq i \leq n$ . We apply P(n) both to the  $A_i$  and  $B_i$ .

Now observe that  $B_i \cap B_j = A_i \cap A_j \cap A_{n+1}$ . Likewise,  $B_i \cap B_j \cap B_k = A_i \cap A_j \cap A_k \cap A_{n+1}$ . Now

$$\begin{aligned} |A_1 \cup A_2 \cup \dots \cup A_{n+1}| &= |A_1 \cup \dots \cup A_n| + |A_{n+1}| + |(A_1 \cup \dots \cup A_n) \cap A_{n+1}| \\ &= |A_1 \cup \dots \cup A_n| + |A_{n+1}| - |B_1 \cup \dots \cup B_n| \\ &= \sum_{i \le n} |A_i| - \sum_{i < j \le n} |A_i \cap A_j| + \dots + |A_{n+1}| \\ &- \sum_{i \le n} |B_i| + \sum_{i < j \le n} |B_i \cap B_j| - \dots \end{aligned}$$

Note 
$$\sum_{i \le n} |B_i| = \sum_{i \le n} |A_i \cap A_{n+1}|$$
. So  $\sum_{i < j \le n} |A_i \cap A_j| + \sum_{i \le n} |B_i| = \sum_{i < j \le n+1} |A_i \cap A_j|$ 
$$= \sum_{i \le n+1} |A_i| - \sum_{i < j \le n+1} |A_i \cap A_j| + \cdots$$

So 
$$P(n) \Rightarrow P(n+1)$$
 for  $n \ge 2$ . By WPI,  $P(n)$  is true for all  $n$ .

**Theorem** (Strong principle of induction). Let P(n) be a statement about  $n \in \mathbb{N}$ . Suppose that

- (i) P(1) is true
- (ii)  $\forall n \in \mathbb{N}$ , if P(k) is true  $\forall k < n$  then P(n) is true.

Then P(n) is true for all  $n \in N$ .

**Theorem.** The strong principle of induction is equivalent to the weak principle of induction.

*Proof.* Clearly the strong principle implies the weak principle since  $[P(n) \Rightarrow P(n+1)] \Rightarrow [(P(1) \land P(2) \land \cdots \land P(n)) \Rightarrow P(n+1)]$ 

Now show that the weak principle implies the strong principle. Suppose that P(1) is true and  $\forall n(P(1) \land P(2) \land \cdots \land P(n-1)) \Rightarrow P(n)$ . We want to show that P(n) is true for all n using the weak principle.

Let Q(n) = "P(k) is true  $\forall k \leq n$ ". Then Q(1) is true. Suppose that Q(n) is true. Then  $P(1) \wedge P(2) \wedge \cdots \wedge P(n)$  is true. So P(n+1) is true. Hence Q(n+1) is true. By the weak principle, Q(n) is true for all n. So P(n) is true for all n.

**Theorem** (Well-ordering principle).  $\mathbb{N}$  is well-ordered under the usual order, i.e. every non-empty subset of  $\mathbb{N}$  has a minimal element.

**Theorem.** The well-ordering principle is equivalent to the strong principle of induction.

*Proof.* First prove that well-ordering implies strong induction. Consider a proposition P(n). Suppose P(k) is true  $\forall k < n$  implies P(n).

Assume the contrary. Consider the set  $S = \{n \in \mathbb{N} : \neg P(n)\}$ . Then S has a minimal element m. Since m is the minimal counterexample to P, P(k) is true

for all k < m. However, this implies that P(m) is true, which is a contradiction. Therefore P(n) must be true for all n.

To show that strong induction implies well-ordering, let  $S \subseteq \mathbb{N}$ . Suppose that S has no minimal element. We need to show that S is empty. Let P(n) be the statement  $n \notin S$ .

Certainly  $1 \notin S$ , or else it will be the minimal element. So P(1) is true. Suppose we know that P(k) is true for all k < n, i.e.  $k \notin S$  for all k < n. Now  $n \notin S$ , or else n will be the minimal element. So P(n) is true. By strong induction, P(n) is true for all n, i.e. S is empty.  $\square$ 

# 4 Modular arithmetic

**Proposition.** If  $a \equiv b \pmod{m}$ , and d|m, then  $a \equiv b \pmod{d}$ .

Proof.  $a \equiv b \pmod{m} \Rightarrow m|a-b \Rightarrow d|a-b \Rightarrow a \equiv b \pmod{d}$ .

**Proposition.** If  $a \equiv b \pmod{m}$  and  $u \equiv v \pmod{m}$ , then  $a + u \equiv b + v \pmod{m}$  and  $au \equiv bv \pmod{m}$ .

*Proof.* Since  $a \equiv b \pmod{m}$  and  $u \equiv v \pmod{m}$ , we have m|(a-b)+(u-v)=(a+u)-(b+v). So  $a+u \equiv b+v \pmod{m}$ 

Since  $a \equiv b \pmod{m}$  and  $u \equiv v \pmod{m}$ , we have m|(a-b)u+b(u-v)=au-bv. So  $au \equiv bv \pmod{m}$ .

**Theorem.** There are infinitely many primes that are  $\equiv -1 \pmod{4}$ .

*Proof.* Suppose not. So let  $p_1, \dots p_k$  be all primes  $\equiv -1 \pmod 4$ . Let  $N = 4p_1p_2 \dots p_k - 1$ . Then  $N \equiv -1 \pmod 4$ . Now N is a product of primes, say  $N = q_1q_2 \dots q_\ell$ . But  $2 \nmid N$  and  $p_i \nmid N$  for all i. So  $q_i \equiv 1 \pmod 4$  for all i. But then that implies  $N = q_1q_2 \dots q_\ell \equiv 1 \pmod 4$ , which is a contradiction.  $\square$ 

**Theorem.** u is a unit modulo m if and only if (u, m) = 1.

*Proof.* ( $\Rightarrow$ ) Suppose u is a unit. Then  $\exists v$  such that  $uv \equiv 1 \pmod{m}$ . Then uv = 1 + mn for some n, or uv - mn = 1. So 1 can be written as a linear combination of u and m. So (u, m) = 1.

 $(\Leftarrow)$  Suppose that (u, m) = 1. Then there exists a, b with ua + mb = 1. Thus  $ua \equiv 1 \pmod{m}$ .

**Corollary.** If (a, m) = 1, then the congruence  $ax \equiv b \pmod{m}$  has a unique (modulo m) solution.

*Proof.* If  $ax \equiv b \pmod{m}$ , and (a, m) = 1, then  $\exists a^{-1}$  such that  $a^{-1}a \equiv 1 \pmod{m}$ . So  $a^{-1}ax \equiv a^{-1}b \pmod{m}$  and thus  $x \equiv a^{-1}b \pmod{m}$ . Finally we check that  $x \equiv a^{-1}b \pmod{m}$  is indeed a solution:  $ax \equiv aa^{-1}b \equiv b \pmod{m}$ .

**Proposition.** There is a solution to  $ax \equiv b \pmod{m}$  if and only if (a, m)|b. If d = (a, m)|b, then the solution is the unique solution to  $\frac{a}{d}x \equiv \frac{b}{d}x \pmod{\frac{m}{d}}$ 

*Proof.* Let d = (a, m). If there is a solution to  $ax \equiv b \pmod{m}$ , then m|ax - b. So d|ax - b and d|b.

On the contrary, if d|b, we have  $ax \equiv b \pmod{m} \Leftrightarrow ax - b = km$  for some  $k \in Z$ . Write a = da', adb' and m = dm'. So  $ax \equiv b \pmod{m} \Leftrightarrow da'x - db' = dkm' \Leftrightarrow a'x - b' = km' \Leftrightarrow a'x \equiv b' \pmod{m'}$ . Note that (a', m') = 1 since we divided by their greatest common factor. Then this has a unique solution modulo m'.

# 4.1 Multiple moduli

**Theorem** (Chinese remainder theorem). Let (m, n) = 1 and  $a, b \in \mathbb{Z}$ . Then there is a unique solution (modulo mn) to the simultaneous congruences

$$\begin{cases} x \equiv a \pmod{m} \\ x \equiv b \pmod{n} \end{cases},$$

i.e.  $\exists x \text{ satisfying both and every other solution is } \equiv x \pmod{mn}$ 

*Proof.* Since (m,n)=1,  $\exists u,v\in\mathbb{Z}$  with um+vn=1. Then  $vn\equiv 1\pmod m$  and  $um\equiv 1\pmod n$ . Put x=umb+vna. So  $x\equiv a\pmod m$  and  $x\equiv b\pmod n$ .

Moreover,

$$y \equiv a \pmod{m}$$
 and  $y \equiv b \pmod{n}$   
 $\Leftrightarrow y \equiv x \pmod{m}$  and  $y \equiv x \pmod{n}$   
 $\Leftrightarrow m|y-x \text{ and } n|y-x$   
 $\Leftrightarrow mn|y-x$   
 $\Leftrightarrow y \equiv x \pmod{mn}$ 

**Proposition.** Given any (m, n) = 1, c is a unit (mod mn) iff c is a unit both mod m and mod n.

*Proof.* ( $\Rightarrow$ ) If  $\exists u$  such that  $cu \equiv 1 \pmod{mn}$ , then  $cu \equiv 1 \pmod{m}$  and  $cu \equiv 1 \pmod{n}$ . So c is a unit mod m and n.

( $\Leftarrow$ ) By CRT,  $\exists w$  with  $w \equiv u \pmod{m}$  and  $w \equiv v \pmod{n}$ . If there exists u, v such that  $cu \equiv 1 \pmod{m}$  and  $cv \equiv 1 \pmod{n}$ , then  $cw \equiv cu \equiv 1 \pmod{m}$  and  $cw \equiv cv \equiv 1 \pmod{n}$ .

But we know that  $1 \equiv 1 \pmod{m}$  and  $1 \equiv 1 \pmod{n}$ , so 1 is a solution to  $cw \equiv 1 \pmod{m}$ ,  $cw \equiv 1 \pmod{n}$  and by the "uniqueness" part of the Chinese remainder theorem, we must have  $cw \equiv 1 \pmod{mn}$ .

#### Proposition.

- (i)  $\phi(m)\phi(n) = \phi(m)\phi(n)$  if (m,n) = 1, i.e.  $\phi$  is multiplicative.
- (ii) If p is a prime,  $\phi(p) = p 1$
- (iii) If p is a prime,  $\phi(p^k) = p^k p^{k-1} = p^k(1 1/p)$
- (iv)  $\phi(m) = m \prod_{n|m} (1 1/p)$ .

*Proof.* Two proofs of (iv):

(i) Suppose  $m = p_1^{k_1} p_2^{k_2} \cdots p_{\ell}^{k_{\ell}}$ . Then

$$\begin{split} \phi(m) &= \phi(p_1^{k_1})\phi(p_2^{k_2})\cdots\phi(p_\ell^{k_\ell}) \\ &= p_1^{k_1}(1 - 1/p_1)p_2^{k_2}(1 - 1/p_2)\cdots p_\ell^{k_\ell}(1 - 1/p_\ell) \\ &= m \prod_{p|m} (1 - 1/p) \end{split}$$

(ii) Let  $m = p_1^{k_1} p_2^{k_2} \cdots p_\ell^{k_\ell}$ . Let  $X = \{0, \cdots m - 1\}$ . Let  $A_j = \{x \in X : p_j | x\}$ . Then  $|X| = m, \ |A_j| = m/p_j, \ |A_i \cap A_j| = m/(p_i p_j)$  etc. So  $\phi(m) = |\bar{A}_1 \cap \bar{A}_2 \cap \cdots \bar{A}_\ell| = m \prod_{p | m} (1 - 1/p)$ 

# 4.2 Prime moduli

**Theorem** (Wilson's theorem).  $(p-1)! \equiv -1 \pmod{p}$  if p is a prime.

*Proof.* If p is a prime, then  $1, 2, \dots, p-1$  are units. Among these, we can pair each number up with its inverse (e.g. 3 with 4 in modulo 11). The only elements that cannot be paired with a different number are 1 and -1, who are self-inverses, as show below:

$$x^{2} \equiv 1 \pmod{p}$$

$$\Leftrightarrow p|(x^{2} - 1)$$

$$\Leftrightarrow p|(x - 1)(x + 1)$$

$$\Leftrightarrow p|x - 1 \text{ or } p|x + 1$$

$$\Leftrightarrow p \equiv \pm 1 \pmod{p}$$

Now (p-1)! is a product of (p-3)/2 inverse pairs together with 1 and -1. So the product is -1.

**Theorem** (Fermat's little theorem). Let p be a prime. Then  $a^p \equiv a \pmod{p}$  for all  $a \in \mathbb{Z}$ . Equivalently,  $a^{p-1} \equiv a \pmod{p}$  if  $a \not\equiv 0 \pmod{p}$ .

*Proof.* Two proofs are offered:

- (i) The numbers  $\{1, 2, \dots, p-1\}$  are units modulo p and form a group of order p-1. So  $a^{p-1} \equiv 1$  by Lagrange's theorem.
- (ii) If  $a \not\equiv 0$ , then a is a unit. So  $ax \equiv ay$  iff  $x \equiv y$ . Then  $a, 2a, 3a, \dots (p-1)a$  are distinct mod p. So they are congruent to  $1, 2, \dots p-1$  in some order. Hence  $a \cdot 2a \cdots 3a \cdots (p-1)a \equiv 1 \cdot 2 \cdot 3 \cdots (p-1)$ . So  $a^{p-1}(p-1)! \equiv (p-1)!$ . So  $a^{p-1} \equiv 1 \pmod{p}$ .

**Theorem** (Fermat-Euler Theorem). Let a, m be coprime. Then

$$a^{\phi(m)} \equiv 1 \pmod{m}$$
.

*Proof.* Lagrange's theorem: The units mod m form a group of size  $\phi(m)$ .

Alternatively, let  $U = \{x \in \mathbb{N} : 0 < x < m, (x, m) = 1\}$ . These are the  $\phi(m)$  units. Since a is a unit,  $ax \equiv ay \pmod{m}$  only if  $x \equiv y \pmod{m}$ . So if  $U = \{u_1, u_2, \cdots, u_{\phi(m)}\}$ , then  $\{au_1, au_2, \cdots au_{\phi(m)}\}$  are distinct and are units. So they must be  $u_1, \cdots u_{\phi(m)}$  in some order. Then  $au_1au_2 \cdots au_{\phi(m)} \equiv u_1u_2 \cdots u_{\phi(m)}$ . So  $a^{\phi(m)}z \equiv z$ , where  $z = u_1u_2 \cdots u_{\phi(m)}$ . Since z is a unit, we can multiply by its inverse and obtain  $a^{\phi(m)} \equiv 1$ .

**Proposition.** If p is an odd prime, then -1 is a quadratic residue if and only if  $p \equiv 1 \pmod{4}$ .

**Proposition.** (Unproven) A prime p is the sum of two squares if and only if  $p \equiv 1 \pmod{4}$ .

**Proposition.** There are infinitely many primes  $\equiv 1 \pmod{4}$ .

Proof. Suppose not, and  $p_1, \dots p_k$  are all the primes  $\equiv 1 \pmod{4}$ . Let  $N = (2p_1 \dots p_k)^2 + 1$ . Then N is not divisible by 2 or  $p_1, \dots, p_k$ . Let q be a prime q|N. Then  $q \equiv -1 \pmod{4}$ . Then  $N \equiv 0 \pmod{q}$  so  $(2p_1 \dots p_k)^2 + 1 \equiv 0 \pmod{q}$ , i.e.  $(2p_1 \dots p_k)^2 \equiv -1 \pmod{q}$ . So -1 is a quadratic residue mod q, which is a contradiction since  $q \equiv -1 \pmod{4}$ .

**Proposition.** Let p = 4k + 3 be a prime. Then if a is a quadratic residue, i.e.  $a \equiv z^2 \pmod{p}$  for some z, then  $z = \pm a^{k+1}$ .

*Proof.* By Fermat's little theorem,  $a^{2k+1} \equiv z^{4k+2} \equiv z^{p-1} \equiv 1$ . If we multiply by a, then  $a^{2k+2} \equiv a \pmod{p}$ . So  $(\pm a^{k+1})^2 \equiv a \pmod{p}$ .

Note: We can compute powers of a efficiently by repeated squaring. e.g. to find  $a^37$ , then  $a^{37} = a^{32}a^4a^1 = ((((a^2)^2)^2)^2 \cdot (a^2)^2 \cdot a$ . Thus calculation of  $a^n$  has time complexity  $O(\log n)$  (as opposed to O(n) if you take powers manually).  $\square$ 

# 4.3 Public-key (Asymmetric) cryptography

## 4.3.1 RSA encryption

**Theorem** (RSA Encryption). We want people to be able to send a message to Bob without Eve eavesdropping. So the message must be encrypted. We want an algorithm that allows anyone to encrypt, but only Bob to decrypt (e.g. many parties sending passwords with the bank).

Let us first agree to write messages as sequences of numbers, e.g. in ASCII or UTF-8.

This is often done with RSA encryption (Rivest, Shamier, Adleman). Bob thinks of two large primes p,q. Let n=pq and pick e coprime to  $\phi(n)=(p-1)(q-1)$ . Then work out d with  $de\equiv 1\pmod{\phi(n)}$  (i.e.  $de=k\phi(n)+1$ ). Bob then publishes the pair (n,e).

For Alice to encrypt a message, Alice splits the message into numbers M < n. Alice sends  $M^e \pmod{n}$  to Bob.

Bob then computes  $(M^e)^d = M^{k\phi(n)+1} \equiv M \pmod{n}$  by Fermat-Euler theorem.

How can Eve find M? We can, of course, factorize n and be in the same position as Bob. However, it is currently assumed that this is hard. Is there any other way? Currently we do not know iff RSA can be broken without factorizing (c.f. RSA problem).

# 5 Real numbers

#### 5.1 Construction of natural numbers

# 5.2 Construction of integers

#### 5.3 Construction of rationals

**Proposition.**  $\mathbb{Q}$  is a totally ordered-field.

**Proposition.**  $\mathbb{Q}$  is densely ordered, i.e.  $\forall p, q \in \mathbb{Q}$  with p < q, then  $\exists r \in \mathbb{Q}(p < r < q)$ , e.g.  $r = \frac{p+q}{2}$ .

**Proposition.** There is no rational  $q \in \mathbb{Q}$  with  $q^2 = 2$ .

*Proof.* Suppose not, and  $(\frac{a}{b})^2 = 2$ , where b is chosen as small as possible.

- (i)  $a^2 = 2b^2$ . So a is even. Let a = 2a'. Then  $b^2 = 2a'^2$ . Then b is even as well, and b = 2b'. But then  $\frac{a}{b} = \frac{a'}{b'}$  with a smaller b'. Contradiction.
- (ii) We know that b is a product of primes if  $b \neq 1$ . Let p|b. Then  $a^2 = 2b^2$ . So  $p|a^2$ . So p|a. Contradict b minimal.
- (iii) (Dirichlet) We have  $\frac{a}{b} = \frac{2b}{a}$ . So  $a^2 = 2b^2$ . For any, u, v, we have  $a^2v = 2b^2v$  and thus  $uab + a^2v = uab + 2b^2v$ . So  $\frac{a}{b} = \frac{au + 2bv}{bu + av}$ . Put u = -1, v = 1. Then  $\frac{a}{b} = \frac{2b a}{a b}$ . Since a < 2b, a b < b. So we have found a rational with smaller b.
- (iv) Same as 3, but pick u, v so bu + av = 1 since a and b are coprime.. So  $\frac{a}{b}$  is an integer.

# 5.4 Construction of real numbers

**Axiom** (Least upper bound axiom). Every non-empty set of the real numbers that has an upper bound has a least upper bound.

Corollary. Every non-empty set of the real numbers bounded below has an infimum

*Proof.*  $-S = \{-x : x \in S\}$  is a non-empty set bounded above, and  $\inf S = -\sup(-S)$ .

**Theorem.** (Axiom of Archimedes) Given  $r \in \mathbb{R}$ , there exists  $n \in \mathbb{N}$  with n > r.

*Proof.* Assume the contrary. Then r is an upper bound for  $\mathbb{N}$ .  $\mathbb{N}$  is not empty since  $1 \in \mathbb{N}$ . By the least upper bound axiom,  $s = \sup \mathbb{N}$  exists. Since s is the least upper bound for  $\mathbb{N}$ , s-1 is not an upper bound for  $\mathbb{N}$ . So  $\exists m \in \mathbb{N}$  with m > s-1. Then  $m+1 \in \mathbb{N}$  but m+1 > s, which contradicts the statement that s is an upper bound.

**Proposition.** inf $\{\frac{1}{n}: n \in \mathbb{N}\} = 0$ . Certainly 0 is a lower bound for S. If t > 0, there exists  $n \in \mathbb{N}$  such that  $n \ge 1/t$ . So  $t \ge 1/n \in S$ . So t is not a lower bound for S.

**Theorem.**  $\mathbb{Q}$  is dense in  $\mathbb{R}$ , i.e. given  $r, s \in \mathbb{R}$ , with r < s,  $\exists q \in \mathbb{Q}$  with r < q < s.

*Proof.* wlog assume first  $r \ge 0$  (just multiply everything by -1 if r < 0). Since s - r > 0,  $\exists n \in \mathbb{N}$ ,  $\frac{1}{n} < s - r$ . By the Axiom of Archimedes,  $\exists N \in \mathbb{N}$  such that N > sn.

Let  $T = \{k \in \mathbb{N} : \frac{k}{n} \ge s\}$ . T is not empty, since  $Nn \in T$ . Then by the well-ordering principle, T has a minimum element m. Now  $m \ne 1$  since  $\frac{1}{n} < s - r \le s$ . Let  $q = \frac{m-1}{n}$ . Since  $m - 1 \not\in T$ , q < s. If  $q = \frac{m-1}{n} < r$ , then  $\frac{m}{n} < r + \frac{1}{n} < s$ , so  $m \not\in T$ , contradiction. So r < q < s.

**Theorem.** There exists  $x \in \mathbb{R}$  with  $x^2 = 2$ .

*Proof.* Let  $S = \{r \in \mathbb{R} : r^2 \le 2\}$ . Then  $0 \in S$  so  $S \ne \emptyset$ . Also  $\forall r \in S(r \le s)$ . So S is bounded above. So  $S = \sup S$  exists and  $S = \sup S$  exists

By trichotomy, either  $x^2 < 2, x^2 > 2$  or  $x^2 = 2$ .

Suppose  $x^2 < 2$ . Let 0 < t < 1. Then consider  $(x+t)^2 = x^2 + 2xt + t^2 < x^2 + 6t + t \le x^2 + 7t$ . Pick  $t < \frac{2-x^2}{7}$ , then  $(x+t)^2 < 2$ . So  $x+t \in S$ . This contradicts the fact that x is an upper bound of x.

Now suppose  $x^2 > 2$ .Let 0 < t < 1. Then consider  $(x - t)^2 = x^2 - 2xt + t^2 \ge x^2 - 6t$ . Pick  $t < \frac{x^2 - 2}{6}$ . Then  $(x - t)^2 > 2$ , so x - t is an upper bound for S. This contradicts the fact that x is the least upper bound of x.

So by trichotomy,  $x^2 = 2$ .

# 5.5 Sequences

**Theorem.** Every bounded monotonic sequence converges.

*Proof.* wlog assume  $a_n$  is increasing. The set  $\{a_n : n \geq 1\}$  is bounded and non-empty. So it has a supremum l (least upper bound axiom). Show that l is the limit:

Given any  $\epsilon > 0$ ,  $l - \epsilon$  is not an upper bound of  $a_n$ . So  $\exists N$  such that  $a_N \geq l - \epsilon$ . Since  $a_n$  is increasing, we know that  $l \geq a_m \geq a_N > l - \epsilon$  for all  $m \geq N$ . So  $\exists N$  such that  $\forall n \geq N$ ,  $|a_n - l| < \epsilon$ . So  $a_n \to l$ .

**Theorem.** Every sequence has a monotonic subsequence.

Proof. Call a point  $a_k$  a "peak" if  $\forall m \geq k(a_m \leq a_k)$ . If there are infinitely many peaks, then they form a decreasing subsequence. If there are only finitely many peaks,  $\exists N$  such that no  $a_n$  with n > N is a peak. Pick  $a_{N_1}$  with  $N_1 > N$ . Then pick  $a_{N_2}$  with  $N_2 > N_1$  and  $a_{N_2} > a_{N_1}$ . This is possible because  $a_{N_1}$  is not a peak. The pick  $a_{N_3}$  with  $N_3 > N_2$  and  $a_{N_3} > a_{N_2}$ , ad infinitum. Then we have a monotonic subsequence.

#### Theorem.

- (i) If  $a_n \to a$  and  $a_n \to b$ , then a = b (i.e. limits are unique)
- (ii) If  $a_n \to a$  and  $b_n = a_n$  for all but finitely many n, then  $b_n \to a$ .
- (iii) If  $a_n = a$  for all n, then  $a_n = a$ .
- (iv) If  $a_n \to a$  and  $b_n \to b$ , then  $a_n + b_n \to a + b$

- (v) If  $a_n \to a$  and  $b_n \to b$ , then  $a_n b_n \to ab$
- (vi) If  $a_n \to a \neq 0$ , and  $\forall n(a_n \neq 0)$ . Then  $1/a_n \to 1/a$ .
- (vii) If  $a_n \to a$  and  $b_n \to a$ , and  $\forall n (a_n \le c_n \le b_n)$ , then  $c_n \to a$ . (Sandwich theorem)

Proof.

- (i) Suppose instead a < b. Then choose  $\epsilon = \frac{b-a}{2}$ . By the definition of the limit,  $\exists N_1 \text{ s.t. } \forall n \geq N_1, \ |a_n-a| < \epsilon$ . There also  $\exists N_2 \text{ s.t. } \forall n \geq N_2, \ |a_n-b| < \epsilon$ . Let  $N = \max\{N_1, N_2\}$ . If  $n \geq \max\{N_1, N_2\}$ , then  $|a-b| \leq |a-a_n| + |a_n-b| < 2\epsilon = b-a$ . Contradiction. So a=b.
- (ii) Given  $\epsilon > 0$ , there  $\exists N_1$  s.t.  $\forall n \geq N_1$ , we have  $|a_n a| < \epsilon$ . Since  $b_n = a_n$  for all but finitely many n, there exists  $N_2$  such that  $\forall n \geq N_2$ ,  $a_n = b_n$ . Let  $N = \max\{N_1, N_2\}$ . Then  $\forall n \geq N$ , we have  $|b_n a| = |a_n a| < \epsilon$ . So  $b_n \to a$ .
- (iii)  $\forall \epsilon$ , take N = 1. Then  $|a_n a| = 0 < \epsilon$  for all  $n \ge 1$ .
- (iv) Given  $\epsilon > 0$ ,  $\exists N_1$  s.t.  $\forall n \geq N_1$ , we have  $|a_n a| < \epsilon/2$ . Similarly,  $\exists N_2$  s.t.  $\forall n \geq N_2$ , we have  $|b_n b| < \epsilon/2$ . Let  $N = \max\{N_1, N_2\}$ . Then  $\forall n \geq N$ ,  $|(a_n + b_n) - (a + b)| \leq |a_n - a| + |b_n - b| < \epsilon$ .
- (v) Given  $\epsilon > 0$ , Then there exists  $N_1, N_2, N_3$  s.t.

$$\forall n \ge N_1 : |a_n - a| < \frac{\epsilon}{2(|b| + 1)}$$

$$\forall n \ge N_2 : |b_n - b| < \frac{\epsilon}{2|a|}$$

$$\forall n \ge N_3 : |b_n - b| < 1 \Rightarrow |b_n| < |b| + 1$$

Then let  $N = \max\{N_1, N_2, N_3\}$ . Then  $\forall n \geq N$ ,

$$|a_n b_n - ab| = |b_n (a_n - a) + a(b_n - b)|$$

$$\leq |b_n||a_n - a| + |a||b_n - b|$$

$$< (|b| + 1)|a_n - a| + |a||b_n - b|$$

$$< \frac{\epsilon}{2} + \frac{\epsilon}{2}$$

$$= \epsilon$$

(vi) Given  $\epsilon > 0$ , then  $\exists N_1, N_2$  s.t.  $|a_n - a| < \frac{|a|^2}{2} \epsilon$  and  $|a_n - a| < \frac{|a|}{2}$ . Let  $N = \max\{N_1, N_2\}$ . The  $\forall n \geq N$ ,

$$\left| \frac{1}{a_n} - \frac{1}{a} \right| = \frac{|a_n - a|}{|a_n||a|}$$

$$< \frac{2}{|a|^2} |a_n - a|$$

$$< \epsilon$$

(vii) By (iii) to (v), we know that  $b_n - a_n \to 0$ . Let  $\epsilon > 0$ . Then  $\exists N$  s.t.  $\forall n \geq N$ , we have  $|b_n - a_n| < \epsilon$ . So  $|c_n - a_n| < \epsilon$ . So  $c_n - a_n \to 0$ . So  $c_n = (c_n - a_n) + a_n \to a$ .

### 5.6 Series

# 5.6.1 Decimal expansions

# 5.7 Irrational numbers

**Proposition.** A number is periodic iff it is rational.

*Proof.* Clearly a periodic decimal is rational: Say  $x=0.7413157157157\cdots$ . Then

$$10^{\ell}x = 10^{4}x$$

$$= 7413.157157 \cdots$$

$$= 7413 + 157 \left( \frac{1}{10^{3}} + \frac{1}{10^{6}} + \frac{1}{10^{9}} + \cdots \right)$$

$$= 7413 + 157 \cdot \frac{1}{10^{3}} \cdot \frac{1}{1 - 1/10^{3}} \in \mathbb{Q}$$

Conversely, let  $x \in \mathbb{Q}$ . Then x has a periodic decimal. Suppose  $x = \frac{p}{2^c 5^d q}$  with (q, 10) = 1. Then  $10^{\max(c,d)}x = \frac{a}{q} = n + \frac{b}{q}$  for some  $a, b, n \in \mathbb{Z}$  and  $0 \le b < q$ . However, since (q, 10) = 1, by Fermat-Euler,  $10^{\phi(q)} \equiv 1 \pmod{q}$ , i.e.  $10^{\phi(q)} - 1 = kq$  for some k. Then

$$\frac{b}{q} = \frac{kb}{kq} = \frac{kb}{999\cdots 9} = kb \left( \frac{1}{10^{\phi(q)}} + \frac{1}{10^{2\phi(q)}} + \cdots \right).$$

Since kb < kq, write  $kb = d_1d_2 \cdots d_{\phi(q)}$ . So  $\frac{b}{q} = 0.d_1d_2 \cdots d_{\phi(q)}d_1d_2 \cdots$  and x is periodic.

#### 5.8 Euler's number

**Proposition.** e is irrational.

*Proof.* Is  $e \in \mathbb{Q}$ ? Suppose  $e = \frac{p}{q}$ . We know  $q \ge 2$  since e is not an integer (it is between 2 and 3). Then  $q!e \in \mathbb{N}$ . But

$$q!e = \underbrace{q! + q! + \frac{q!}{2!} + \frac{q!}{3!} + \dots + \frac{q!}{q!}}_{n} + \underbrace{\frac{q!}{(q+1)!} + \frac{q!}{(q+2)!} + \dots}_{x},$$

where  $n \in \mathbb{N}$ . We also have

$$x = \frac{1}{q+1} + \frac{1}{(q+1)(q+2)} + \cdots$$

We can bound it by

$$0 < x < \frac{1}{q+1} + \frac{1}{(q+1)^2} + \frac{1}{(q+1)^3} = \frac{1}{q+1} \cdot \frac{1}{1-1/(q+1)} = \frac{1}{q} < 1.$$

This is a contradiction since q!e must be in  $\mathbb N$  but it is a sum of an integer n plus a non-integer x.

# 5.9 Algebraic numbers

**Proposition.** All rational numbers are algebraic.

*Proof.* Let 
$$x = \frac{p}{q}$$
, then x is a root of  $qx - p = 0$ .

**Theorem.** (Liouville 1851; Non-examinable) L is transcendental, where

$$L = \sum_{n=1}^{\infty} \frac{1}{10^{n!}} = 0.11000100 \cdots$$

with 1s in the factorial positions.

*Proof.* Suppose instead that f(L) = 0 where  $f(x) = a_k x^k + a_{k-1} x^{k-1} + \cdots + a_0$ , where  $a_i \in \mathbb{Z}$ ,  $a_k \neq 0$ .

For any rational p/q, we have

$$f\left(\frac{p}{q}\right) = a_k \left(\frac{p}{q}\right)^k + \dots + a_0 = \frac{\text{integer}}{q^k}.$$

So if p/q is not a root of f, then  $f(p/q) \ge q^{-k}$ .

For any m, we can write L = first m terms + rest of the terms = s + t. Now consider |f(s)| = |f(L) - f(s)| (since f(L) = 0). We have

$$|f(L) - f(s)| = \left| \sum a_i (L^i - s^i) \right|$$

$$\leq \sum |a_i (L^i - s^i)|$$

$$= \sum |a_i| (L - s) (L^{i-1} + \dots + s^{i-1})$$

$$\leq \sum |a_i| (L - s)i,$$

$$= (L - s) \sum i |a_i|$$

$$= tC$$

with  $C = \sum i |a_i|$ .

Writing s as a fraction, its denominator is at most  $10^{m!}$ . So  $|f(s)| \ge 10^{-k \times m!}$ . Combining with the above, we have  $tC \ge 10^{-k \times m!}$ .

We can bound t by

$$t = \sum_{j=m+1}^{\infty} 10^{-j!} \le \sum_{\ell=(m+1)!}^{\infty} 10^{\ell} = \frac{10}{9} 10^{-(m+1)!}.$$

So  $(10C/9)10^{-(m+1)!} \ge 10^{-k \times m!}$ . Pick  $m \in \mathbb{N}$  so that  $m \ge k$  and  $10^{m!} > \frac{10C}{9}$ . This is always possible since both k and 10C/9 are constants. Then the inequality gives  $10^{-(m+1)} \ge 10^{-k}$ , which is a contradiction since  $m \ge k$ .

**Theorem.** (Hermite 1873) e is transcendental.

**Theorem.** (Lindermann 1882)  $\pi$  is transcendental.

# 6 Countability

**Lemma.** If  $f:[n] \to [n]$  is injective, then f is surjective.

*Proof.* Perform induction on n: It is true for n=1. Suppose n>1. Let j=f(n). Let  $g:[n]\to [n]$  s.t. g(j)=n, g(n)=j, and g(i)=i otherwise. Then g is a bijection. The map  $g\circ f$  is injective. It fixes n, i.e.  $g\circ f(n)=n$ . So the map  $h:[n-1]\to [n-1]$  by  $h(i)=g\circ f(i)$  is well-defined and injective. So h is surjective. So h is bijective. So h is bijective.

**Corollary.** If A is a set and  $f: A \to [n]$  and  $g: A \to [m]$  are both bijections, then m = n.

*Proof.* wlog assume  $m \ge n$ . Let  $h: [n] \to [m]$  with h(i) = i, which is injective. Then the map  $h \circ f \circ g^{-1}: [m] \to [m]$  is injective. Then by the lemma this is surjective. So h must be surjective. So  $n \ge m$ . Hence n = m.

**Lemma.** Let  $S \subseteq \mathbb{N}$ . Then either S is finite or there is a bijection  $g : \mathbb{N} \to S$ .

Proof. If  $S \neq \emptyset$ , by the well-ordering principle, there is a least element  $s_1 \in S$ . If  $S \setminus \{s_1\} \neq \emptyset$ , it has a least element  $s_2$ . If  $S \setminus \{s_1, s_2\}$  is not empty, there is a least element  $s_3$ . If at some point the process stops, then  $S = \{s_1, s_2, \dots, s_n\}$ , which is finite. Otherwise, if it goes on forever, the map  $g : \mathbb{N} \to S$  given by  $g(i) = s_i$  is well-defined and is an injection. It is also a surjection because if  $k \in S$ , then k is a natural number and there are at most k elements of k less than k. So k will be mapped to for some k.

**Theorem.** The following are equivalent:

- (i) A is countable
- (ii) There is an injection from  $A \to \mathbb{N}$
- (iii)  $A = \emptyset$  or there is a surjection from  $\mathbb{N} \to A$

*Proof.* (i)  $\Rightarrow$  (iii): If A is finite, there is a bijection  $f: A \to S$  for some  $S \subseteq \mathbb{N}$ . For all  $x \in \mathbb{N}$ , if  $x \in S$ , then map  $x \mapsto f^{-1}(x)$ . Otherwise, map x to any element of A. This is a surjection since  $\forall a \in A$ , we have  $f(a) \mapsto a$ .

- (iii)  $\Rightarrow$  (ii): If  $A \neq \emptyset$  and  $f : \mathbb{N} \to A$  is a surjection. Define a map  $g : A \to \mathbb{N}$  by  $g(a) = \min f^{-1}(\{a\})$ , which exists by well-ordering. So g is an injection.
- (ii)  $\Rightarrow$  (i): If there is an injection  $f: A \to \mathbb{N}$ , then f gives a bijection between A and  $S = f(A) \subseteq \mathbb{N}$ . If S is finite, so is A. If S is infinite, there is a bijection g between S and  $\mathbb{N}$ . So there is a bijection  $g \circ f$  between A and  $\mathbb{N}$ .

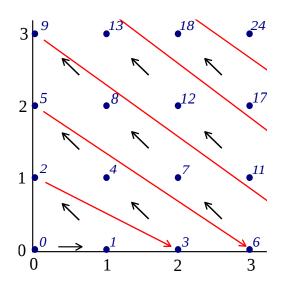

**Proposition.** The integers  $\mathbb{Z}$  are countable.

*Proof.* The map  $f: \mathbb{Z} \to \mathbb{N}$  given by

$$f(n) = \begin{cases} 2n & n > 0 \\ 2(-n) + 1 & n \le 0 \end{cases}$$

is a bijection.

**Proposition.**  $\mathbb{N} \times \mathbb{N}$  is countable.

Credits: Wikimedia Commons: Cronholm144 CC-BY-SA 3.0

*Proof.* We can map  $(a,b) \mapsto 2^a 3^b$  injectively by the fundamental theorem of arithmetic. So  $\mathbb{N} \times \mathbb{N}$  is countable.

We can also have a bijection  $(a,b)\mapsto {a+b\choose 2}-a+1$ :

**Proposition.** If  $A \to B$  is injective and B is countable, then A is countable (since we can inject  $B \to \mathbb{N}$ ).

**Proposition.**  $\mathbb{Z}^k$  is countable for all  $k \in \mathbb{N}$ 

*Proof.* By induction:  $\mathbb{Z}$  is countable. If  $\mathbb{Z}^k$  is countable,  $\mathbb{Z}^{k+1} = \mathbb{Z} \times \mathbb{Z}^k$ . Since we can map  $\mathbb{Z}^k \to \mathbb{N}$  injectively by the induction hypothesis, we can map injectively  $\mathbb{Z}^{k+1} \to \mathbb{Z} \times \mathbb{N}$ , and we can map that to  $\mathbb{N}$  injectively.

**Theorem.** A countable union of countable sets is countable.

*Proof.* Let I be a countable index set, and for each  $\alpha \in I$ , let  $A_{\alpha}$  be a countable set. We need to show that  $\bigcup_{\alpha \in I} A_{\alpha}$  is countable. It is enough to construct an injection  $h:\bigcup_{\alpha \in I} A_{\alpha} \to \mathbb{N} \times \mathbb{N}$  because  $\mathbb{N} \times \mathbb{N}$  is countable. We know that I is countable. So there exists an injection  $f:I \to \mathbb{N}$ . For each  $\alpha \in I$ , there exists an injection  $g_{\alpha}:A_{\alpha} \to \mathbb{N}$ .

For  $a \in \bigcup A_{\alpha}$ , pick  $m = \min\{j \in \mathbb{N} : a \in A_{\alpha} \text{ and } f(\alpha) = j\}$ . This number exists by the well-ordering principle. Let  $f(\alpha) = m$ . ( $\alpha$  is unique because f is injective) Then  $h(\alpha) = (m, g_{\alpha}(a))$  is an injection.

**Proposition.**  $\mathbb{Q}$  is countable.

*Proof.* It can be proved in two ways:

- (i)  $\mathbb{Q} = \bigcup_{n \geq 1} \frac{1}{n} \mathbb{Z} = \bigcup_{n \geq 1} \left\{ \frac{m}{n} : m \in \mathbb{Z} \right\}$ , which is a countable union of countable sets.
- (ii)  $\mathbb Q$  can be mapped injectively to  $\mathbb Z\times\mathbb N$  by  $a/b\mapsto (a,b),$  where b>0 and (a,b)=1.

**Theorem.** The set of algebraic numbers is countable.

*Proof.* Let  $\mathcal{P}_k$  be the set of polynomials of degree k with integer coefficients. Then  $a_k x^k + a_{k-1} x^{k-1} + \cdots + a_0 \mapsto (a_k, a_{k-1}, \cdots, a_0)$  is an injection  $\mathcal{P}_k \to \mathbb{Z}^{k+1}$ . Since  $\mathbb{Z}^{k+1}$  is countable, so is  $\mathcal{P}_k$ .

Let  $\mathcal{P}$  be the set of all polynomials with integer coefficients. Then clearly  $\mathcal{P} = \bigcup \mathcal{P}_k$ . This is a countable union of countable sets. So  $\mathcal{P}$  is countable.

For each polynomial  $p \in \mathcal{P}$ , let  $R_p$  be the set of its roots. Then  $R_p$  is finite and thus countable. Hence  $\bigcup_{p \in \mathcal{P}} R_p$ , the set of all algebraic numbers, is countable.

**Theorem.** The set of real numbers  $\mathbb{R}$  is uncountable.

*Proof.* (Cantor's diagonal argument) Assume  $\mathbb{R}$  is countable. Then we can list the reals as  $r_1, r_2, r_3 \cdots$  so that every real number is in the list. Write each  $r_n$  uniquely in decimal form (i.e. without infinite trailing '9's). List them out vertically:

$$r_1 = n_1 \cdot d_{11} d_{12} d_{13} d_{14} \cdots$$
  
 $r_2 = n_2 \cdot d_{21} d_{22} d_{23} d_{24} \cdots$   
 $r_3 = n_3 \cdot d_{31} d_{32} d_{33} d_{34} \cdots$   
 $r_4 = n_4 \cdot d_{41} d_{42} d_{43} d_{44} \cdots$ 

Define r = 0.  $d_1 d_2 d_3 d_4 \cdots$  by  $d_n = \begin{cases} 0 & d_{nn} \neq 0 \\ 1 & d_{nn} = 0 \end{cases}$ . Then by construction, this differs from the nth number in the list by the nth digit, and is so different from every number in the list. Then r is a real number but not in the list. Contradiction.

Corollary. There are uncountable many transcendental numbers.

*Proof.* If not, then the reals, being the union of the transcendentals and algebraic numbers, must be countable. But the reals is uncountable.  $\Box$ 

**Theorem.** Let A be a set. Then there is no surjection from  $A \to \mathcal{P}A$ .

*Proof.* Suppose  $f: A \to \mathcal{P}(A)$  surjectively. Let  $S = \{a \in A : a \notin f(a)\}$ . Since f is surjective, there must exist  $s \in A$  such that f(s) = S. If  $s \in S$ , then  $s \notin S$  by the definition of S. Conversely, if  $s \notin S$ , then  $s \in S$ . Contradiction. So f cannot exist.

**Theorem** (Cantor-Schröder-Bernstein theorem). Suppose there are injections  $A \to B$  and  $B \to A$ . Then there's a bijection  $A \leftrightarrow B$ .
